FOREWORD

This report discusses the application of the "stress-strength" technique for estimating the reliability of a particular fabric to parameters for which a significant amount of data was available. This work is a continuation of the study of reliability, as related to textile material, which was presented in a technical report entitled, "The Application of the Concept of Reliability to Textile Products", by Dr. Stephen J. Kennedy and Mr. Louis I. Weiner of these Laboratories (NLABS Technical Report 68-23-CM, September 1967).

The "stress-strength" method of analysis used is a statistical technique for determining with test data the probability that characteristics of a product will fall within previously established specification limits. This method appeared to be more applicable to the selected fabric parameters than the more generally associated "time to failure" concept of reliability.

Acknowledgment is made to Mr. Louis I. Weiner for his guidance and review of this work, and to Mr. Daniel daLuz for furnishing the test data used in this analysis.

ABSTRACT

Reliability analyses are made on physical characteristics of a cotton duck material (with a fire, weather, water, mildew - resistant treatment) used in the construction of military tentage and equipage items. The breaking strength in both the lengthwise (warp) direction and crosswise (filling) direction and also the water resistance property were selected as critical characteristics for analyses. The reliability analyses relate to a commodity situation where these techniques may be useful in assessing how well characteristics of a commercial material meet established requirements. The Chi Square (x²) test for goodness of fit was used to test normality of the distribution of laboratory data for each of the characteristics evaluated. Different methods are used to obtain one-sided lower reliability limits. Point estimates of reliability are also computed. Results of the different methods are compared, and the relative advantages of these methods are discussed.

RELIABILITY OF SOME CRITICAL PERFORMANCE CHARACTERISTICS OF COTTON DUCK FABRIC

1. Introduction

Reliability is generally associated with a "time to failure" criterion and would thus be defined as the probability that an item will perform successfully for a specified time under specific conditions of usage. Time is a critical parameter in these applications. The use of a "time to failure" criterion to establish reliability for textile materials may be very limited. These materials, however, present commodity situations where the "stress-strength" analysis technique offers more meaningful information, e.g., the probability that a critical performance characteristic will fall within specification limits. (1) The determination of reliability is dependent directly upon some specific level of performance for textile materials. The performance level selected is customarily an engineering estimate and may be modified to be consistent with production capabilities and/or field serviceability needs.

This report is concerned with the application of reliability techniques (2) (3) in predicting performance reliability of a basket weave cotton duck with a fire, weather, water, mildew-resistant treatment. The parameters selected for evaluation are the breaking strength in the warp and filling directions, and also the water resistance property. These strength characteristics are directly related to durability, while water resistance is an important criteria for functionality.

2. Methodology for Computing Estimates of Reliability

Data were acquired from tests of duck fabric produced by five different manufacturers. A histogram was constructed for each strength factor using a total of 425 individual test results in each instance (Figs 1 and 2). The class interval for each distribution is 10 breaking strength units expressed in pounds.

Both sets of strength data appeared to typify the characteristic bell-shape of a normal distribution. This assumption was also supported by the Chi Square (x^2) goodness of fit tests as shown in Appendices A and B. Accordingly, the methods (2) (3) used in this study to derive reliability point estimates and confidence limits are those applicable to data from a normal population.

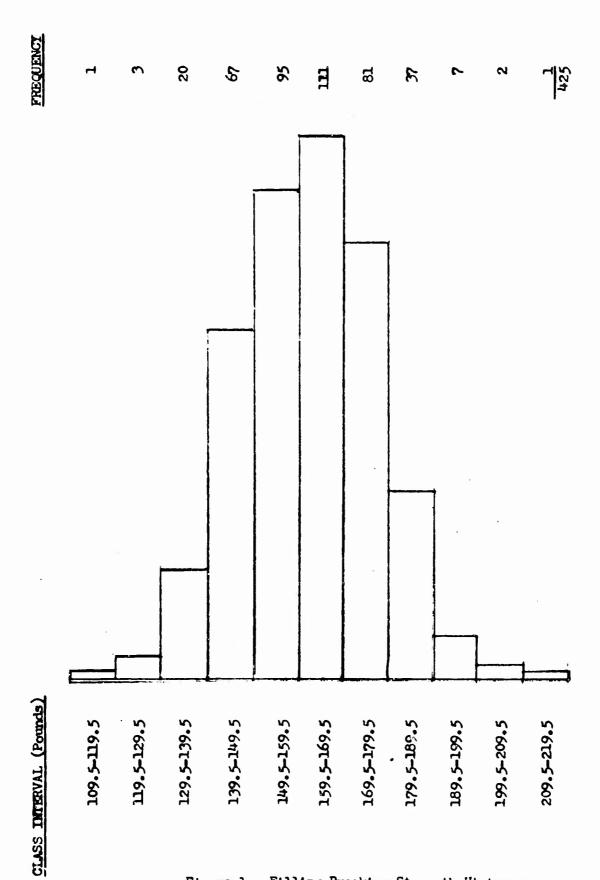

Figure 1. Filling Breaking Strength Histogram

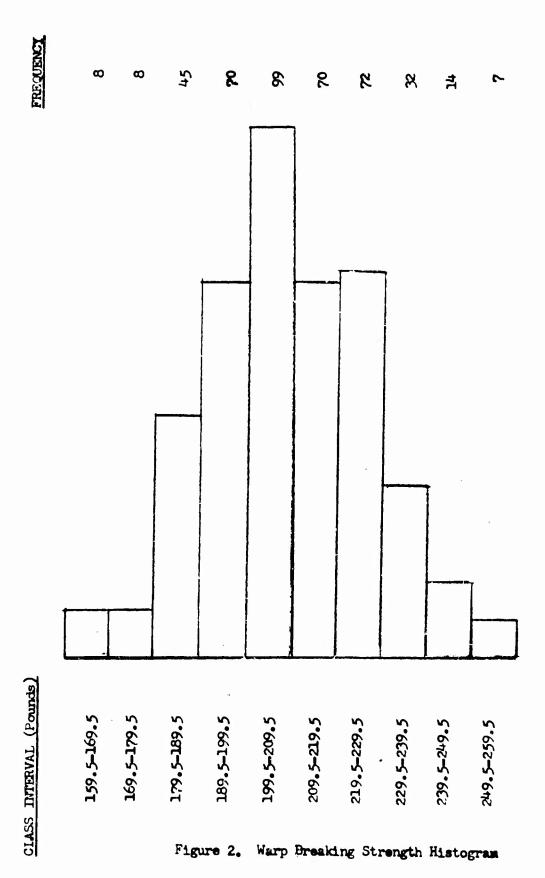

Figure 3 is a histogram showing data for the water resistance property of the duck material. It is apparent that the profile of the histogram does not suggest normality. In this case, the use of the methods discussed here for reliability would be misleading. However, the 200 cc being the maximum amount of water penetration permitted by the specification, reliability point estimate can be obtained by the ratio of total number of values not exceeding 200 cc to the total number of values, as follows:

Reliability, in this case, is the probability that the duck material will permit not more than 200 cc of water penetration when subjected to the specification test. Compliance with this performance characteristic will occur 93 percent of the time. However, no confidence level can be associated with this reliability estimate.

The breaking strength requirements for duck in MIL-C-41808A are 150 pounds for the warp direction and 140 pounds for the filling direction. Since these requirements are cited on a minimum basis, it is appropriate to consider reliability in terms of a one-sided lower limit. Breaking strength values falling above the minimum specified would indicate successful performance of the material for this characteristic.

The procedure for deriving a point estimate of reliability from data representing a normal distribution requires the computation of the standard normal deviate (k) as follows:

$$k = \frac{\overline{y} - L}{S}$$

where:

$$\bar{x}$$
 = mean breaking strength (1)

L = specification lower limit or minimum

S = standard deviation

The standard normal deviate is used to obtain the percent area in a normal distribution which exceeds the specification minimum (Fig. 4). This area is the probability that a strength value will meet the performance requirement. This probability is also the point estimate of reliability, and may be obtained from a cumulative normal distribution table (4) which is included in most statistical texts.

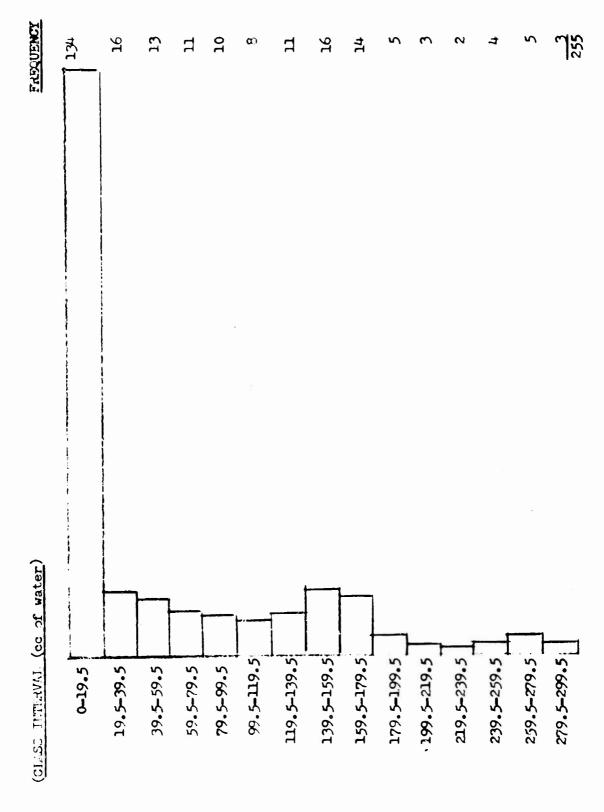

Figure 3. Water Resistance Histogram

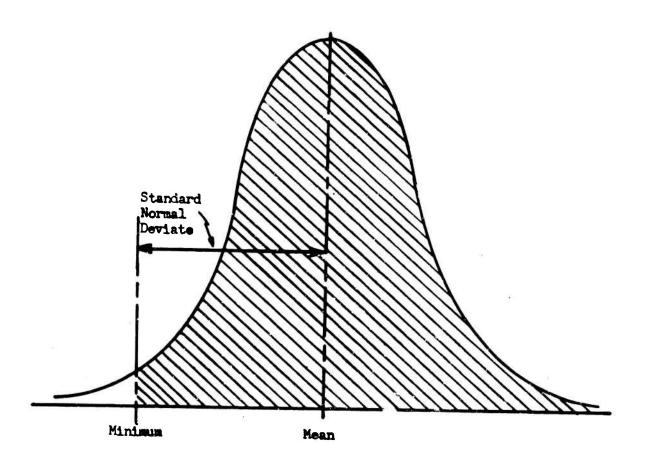

Figure 4. Area Under Normal Curve

By means of a lower reliability limit based on a confidence level, a more precise statement can be made about reliability. One-sided lower reliability limits were computed for the strength factors as shown in Appendices A and B. The first method of establishing the lower limit with a 95 percent confidence was found by computing KRL from the following formulae:

Method 1

$$K_{RL} = k-A \tag{2}$$

$$A = K(1 - Y) \left[\frac{1}{n} + \frac{k^2}{2n-2} \right]^{\frac{1}{2}}$$
 (3)

A further definition of the quantities in equation (3) is:

 $K(1-\gamma)$ = represents the standard normal deviate for a particular confidence level. Since the 95 percent one-sided confidence level was used in this study, $K(1-\gamma) = K(1-.95)$ = K(.05) = 1.645. This value was obtained from the cumulative normal distribution table.

n = number of test specimens (values)

k = standard normal deviate computed by equation (1)

The quantity KRI is the standard normal deviate for the lower one-sided reliability limit. By entering this value in the cumulative normal distribution table, (4) the lower reliability limit at the 95 percent confidence level is obtained.

The lower one-sided limit for reliability can also be established by a second, more involved method which is based on the non-central t-statistic(3). The mathematical relationships are as follows:

Method 2

$$k^2$$
 (a) - 2k (K \propto) + b = 0 (4)

$$a = 1 - K_{\gamma}^2/2(n - 1)$$
 (5)

$$b = K_{\propto}^2 - K_{\gamma}^2/n \tag{6}$$

whore: Ke = standard normal deviate of the lower one-sided reliability limit.

k = standard normal deviate of the reliability
point estimate. This value is derived by
equation (1)

Ky = standard normal deviate for the 95 percent confidence level which is equal to 1.645.

n = number of test specimens (values)

By solving equations (5) and (6) and substituting in equation (4), the standard normal deviate (K \prec) is obtained and can be converted to the lower reliability limit by entering the K \sim value in the cumulative normal distribution table (4).

3. Results

The reliability limit calculations using the two methods are shown in Appendices A and B and the results are summarized in Table I. The reliability of the filling breaking strengths is 91.5 percent at the 95 percent confidence level. There is a 95 percent assurance that at least 91.5 percent of the duck fabrics will have breaking strengths above the minimum specification requirement (140 pounds). Actually, 401 breaking strength values of the 425 total were above the minimum.

The reliability of the warp breaking strength is 99.9 percent. Thus, 95 percent of the time, at least 99.9 percent of the duck fabrics can be expected to have warp breaking strengths above the specification requirement (150 pounds). For this particular data, all duck fabrics tested had strength values above the specification minimum.

4. Summary

Reliability estimates obtained by both methods were the same. Method 1, however, is the method of choice since it is simpler, involving fewer computations.

This study has shown that the warp and filling breaking strength and water resistance requirements for cotton duck fabrics are consistent with manufacturing capabilities. Reliability analyses provide a quantitative means to assess, with assurance.

how well materials are meeting requirements. Similar analysis of other fabric characteristics such as tearing strength, wind resistance, and shrinkage may be feasible and should be investigated.

The data for this study were pooled from several sources. Similar analyses may be made for individual sources (suppliers), and would serve to assess the capability of each source to meet established requirements.

TABLE I

RELIAPILITY OF BREAKING STRENGTH OF A COTTON DUCK*

	Warp (%)	Filling (%)
Method 1	99•9	91.5
Method 2	99.9	91.5

Based on one-sided 95 percent limit

209.5-219.5	5	425	_5_l -117	25 965

$$\vec{x} = -\frac{117}{425} = -.275$$

$$\vec{x} = 164.5 - [(.275)(10)] = 161.75$$

$$s^2 = \frac{965 - \frac{(-117)^2}{425}}{424} = 2.20$$

$$S = (\sqrt{2.20})(10) = 14.8$$

2. Calculation of Chi Square Test for Goodness of Fit to a Normal Distribution

	7	J			
<u>Interval</u>	<u>I - </u>	Relative Freq.	Theoretical Freq. F2		$\frac{(\mathbf{f} - \mathbf{F})^2}{\mathbf{F}}$
119.5 or less	-2.85	.0022	0.9	1	500
119.5-129.5	-2.18	.0147	5.3	3	.780
129.5-139.5	-1.50	.0668	22.2	20	.218
139.5-149.5	-0.83	.2000	56.6	67	1.910
149.5-159.5	-0.15	.4400	102.0	95	0.480
159.5-169.5	0.52	.7100	114.8	m	0.127
169.5-179.5	1.20	.8849	74.3	81	.604
177.5-189.5	1.88	.9640	33.6	37_	•345
189.5-199.5	2.56	•9940	12.8	7	1.835
199.5-209.5	3.23	•9992	2.1	2	
above-209.5			.4 .4	1	
			425		6.299

- 1) The letter I is the upper value of each class interval
- The theoretical frequency is obtained by multiplying the relative frequency for each interval by 425 and subtracting from this result the theoretical frequency for the preceding interval. For example, for the 119.5-129.5 interval, multiply (.0147)(425) = 6.2. Subtract 0.9 from 6.2 to obtain 5.3, as shown above.
- The theoretical frequency for any interval should not be less than 5.0. χ^2 (.95), (5) = 11.07

Since 11.07 > 6.299, there is no reason to reject the assumption that the data represent a normal distribution at 95 percent significance level with 5 degrees of freedom.

3. Calculation of Point Estimate of Reliability

$$k = \frac{\bar{x} - L}{S} = \frac{161.75 - 140}{14.8} = 1.47$$
 $R = 92.94 \text{ (From Tables)}$

4. Reliability at 95 Percent Confidence Level (One-Sided Lower Limit)

Method 1

$$K_{RL} = k - A$$

$$A = K(1 - \gamma) \left[\frac{1}{n} + \frac{k^2}{2n - 2} \right]^{\frac{1}{2}}$$

At 95 Percent Confidence Level

$$K(1 - \gamma) = K(1 - .95) = K_{.05} = 1.645$$
 (Tables)

 $n = 425$
 $k = 1.47$
 $A = 1.645 \left[\frac{1}{425} + \frac{(1.47)}{648} \right]^{\frac{1}{2}} = 0.115$
 $K_{RL} = 1.47 - 0.115 = 1.355$
 $RL = 91.5\%$ (From Tables)

Method 2

$$k^2a - 2kK_{a} + b = 0$$

$$k = 1.47$$

$$a = 1 - \frac{(1.645)^2}{2(424)} = .99687$$

$$b = K^2 - .006$$

$$(1.47)^2 (.99687) - 2(1.47) K_{\chi} + K_{\chi}^2 - .006 = 0$$

$$2.154 - 2.94 \text{ K}_{\infty} + \text{ K}_{\infty}^2 - .006 = 0$$

$$K^2 \sim -2.94 K \sim +2.148 = 0$$

$$K = \frac{-b}{2a} + \frac{1}{\sqrt{b^2} - \frac{1}{2a}}$$

$$K_{\sim} = \frac{2.94 \pm \sqrt{(2.94)^2 - 4(1)(2.148)}}{2}$$

APPENDIX B

WARP BREAKING STRENGTH

1. Calculation of Mean and Standard Deviation

	Coded Score (x)	f	fx	fx^2
159.5-169.5	_/;	8	-32	128

239.5-249.5	2.23	•9870	14.2	14	0.003
above 249.5	2.78	•9972	<u>5.7</u> 425	7	0.295 12.679

$$\chi^2$$
 .95(ν) = 14.07

14.07 > 12.68

Since 14.07 > 12.68, there is no reason to reject the assumption that the data represent a normal distribution at 95 percent significance level with 7 degrees of freedom.

3. Calculation of Point Estimate of Reliability

$$k = \frac{\overline{X} - L}{S} = \frac{208.85 - 150}{18.2} = 3.230$$

Method 1

$$K_{RL} = k - A$$

$$A = K(1 - 1) \left[\frac{1}{n} + \frac{k^2}{2n - 2} \right]^{\frac{1}{2}}$$

At 95 Percent Confidence Level

$$K(1 - \gamma) = K(1 - .95) = K_{.05} = 1.645 \text{ (From Tables)}$$

$$n = 425$$

$$k = 3.23$$

$$A = 1.645 \left[\frac{1}{425} + \frac{(3.23)^2}{848} \right]^{\frac{1}{2}} = 0.199$$

$$K_{RL} = 3.230 - 0.199 = 3.031$$

Method 2

$$k^2a - 2kK + b = 0$$

$$k = 3.23$$

$$a = 1 - \frac{(1.645)^2}{2(424)} = .99687$$

$$b = K_{\infty}^2 - .006$$

$$(3.23)^2 (.99687) - 2(3.23) K_{\checkmark} + K_{\checkmark}^2 - .006 = 0$$

$$10.400 - 6.46K + K^2 - .006 = 0$$

$$K^2 \sim 6.46 \text{ K} + 10.394 = 0$$

$$X_{\infty} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$$K_{\infty} = \frac{6.46}{2} + \frac{1}{2} \times \frac{1000}{2} = \frac{4(1)(10.394)}{2}$$

$$R = 99.\%$$

Reliability analyses are made on physical characteristics of a cotton duck material used in the construction of military tentage and equipage items. The breaking strength in both the lengthwise (warp) direction and crosswise (filling) direction and also the water resistance property were selected as critical characteristics for analyses. The reliability analyses relate to a commodity situation where these techniques may be useful in assessing how well characteristics of a duck material meet established requirements. The Chi Square (x2) test for goodness of fit was used to test normality of the distribution of laboratory data for each of the characteristics evaluated. Different methods are used to obtain one-sided lower reliability limits. Point estimates of reliability are also computed. Results of the different methods are compared, and the relative advantages of these methods are discussed.
